

Name: Carag, Carl Jervie B.	Date Performed: 8/15/25
Course/Section: CPE212/ CPE31S2	Date Submitted: 8/15/25
Instructor: Engr. Robin Valenzuela	Semester and SY: 1st Sem 2025-2026

Activity 2: SSH Key-Based Authentication and Setting up Git

1. Objectives:

- 1.1 Configure remote and local machine to connect via SSH using a KEY instead of using a password
- 1.2 Create a public key and private key
- 1.3 Verify connectivity
- 1.4 Setup Git Repository using local and remote repositories
- 1.5 Configure and Run ad hoc commands from local machine to remote servers

Part 1: Discussion

It is assumed that you are already done with the last Activity (**Activity 1: Configure Network using Virtual Machines**). *Provide screenshots for each task.*

It is also assumed that you have VMs running that you can SSH but requires a password. Our goal is to remotely login through SSH using a key without using a password. In this activity, we create a public and a private key. The private key resides in the local machine while the public key will be pushed to remote machines. Thus, instead of using a password, the local machine can connect automatically using SSH through an authorized key.

What Is ssh-keygen?

Ssh-keygen is a tool for creating new authentication key pairs for SSH. Such key pairs are used for automating logins, single sign-on, and for authenticating hosts.

SSH Keys and Public Key Authentication

The SSH protocol uses public key cryptography for authenticating hosts and users. The authentication keys, called SSH keys, are created using the keygen program.

SSH introduced public key authentication as a more secure alternative to the older .rhosts authentication. It improved security by avoiding the need to have password stored in files and eliminated the possibility of a compromised server stealing the user's password.

However, SSH keys are authentication credentials just like passwords. Thus, they must be managed somewhat analogously to usernames and passwords. They should have a proper termination process so that keys are removed when no longer needed.

Task 1: Create an SSH Key Pair for User Authentication

1. The simplest way to generate a key pair is to run **ssh-keygen** without arguments. In this case, it will prompt for the file in which to store keys. First,

-keygenthe tool asked where to save the file. SSH keys for user authentication are usually stored in the users .ssh directory under the home directory. However, in enterprise environments, the location is often different. The default key file name depends on the algorithm, in this case *id_rsa* when using the default RSA algorithm. It could also be, for example, *id_dsa* or *id_ecdsa*.

```
cj@Workstation:~$ ssh-keygen
Generating public/private ed25519 key pair.
Enter file in which to save the key (/home/cj/.ssh/id_ed25519):
Enter passphrase (empty for no passphrase):
Enter same passphrase again:
Your identification has been saved in /home/cj/.ssh/id_ed25519
Your public key has been saved in /home/cj/.ssh/id_ed25519.pub
The key fingerprint is:
SHA256:7080NgssZhK9Nl2N0DhBIAhtTstEMXwq14bZZSJqL4w cj@Workstation
The key's randomart image is:
+-- [ED25519 256] --+
| =+=+o
| ..B.o+o
| B X++.
| oo0 +o +
| =oo. o S
| E+ = . .
| . O + .
| = o .+ o
| ...+..o
+--- [SHA256] ---+
cj@Workstation:~$
```

2. Issue the command ***ssh-keygen -t rsa -b 4096***. The algorithm is selected using the **-t** option and key size using the **-b** option.

```
cj@Workstation:~$ ssh-keygen -t rsa -b 4096
Generating public/private rsa key pair.

Enter file in which to save the key (/home/cj/.ssh/id_rsa): Enter pass
pty for no passphrase):
Enter same passphrase again:
Your identification has been saved in /home/cj/.ssh/id_rsa
Your public key has been saved in /home/cj/.ssh/id_rsa.pub
The key fingerprint is:
SHA256:iA60TGblT02q5DNbx5MDbFXnRwgE10F/2mr5tzcQlbE cj@Workstation
The key's randomart image is:
+---[RSA 4096]---+
|   .o+=o...   .o|
|   . o.o...   o.|
|   o o . . . .E|
|   * o. . . . |
| +.*... S. . . |
| =o.o+ . + . |
| .o.o.* ... . |
|ooo . o o. . o |
| ++       .....o .|
+---[SHA256]---+
cj@Workstation:~$
```

- When asked for a passphrase, just press enter. The passphrase is used for encrypting the key, so that it cannot be used even if someone obtains the private key file. The passphrase should be cryptographically strong.
- Verify that you have created the key by issuing the command `ls -la .ssh`. The command should show the .ssh directory containing a pair of keys. For example, id_rsa.pub and id_rsa.

```
cj@Workstation:~$ ls -la .ssh
total 28
drwx----- 2 cj cj 4096 Aug 15 09:17 .
drwxr-x--- 15 cj cj 4096 Aug  8 10:40 ..
-rw----- 1 cj cj     0 Aug  8 09:00 authorized_keys
-rw----- 1 cj cj   411 Aug 15 09:15 id_ed25519
-rw-r--r-- 1 cj cj    96 Aug 15 09:15 id_ed25519.pub
-rw----- 1 cj cj  3381 Aug 15 09:17 id_rsa
-rw-r--r-- 1 cj cj   740 Aug 15 09:17 id_rsa.pub
-rw-r--r-- 1 cj cj   852 Aug  8 10:30 known_hosts
cj@Workstation:~$
```

Task 2: Copying the Public Key to the remote servers

- To use public key authentication, the public key must be copied to a server and installed in an *authorized_keys* file. This can be conveniently done using the *ssh-copy-id* tool. ssh

```
cj@Workstation:~$ ssh-copy-id
Usage: /usr/bin/ssh-copy-id [-h|-?|-f|-n|-s|-x] [-i [identity_file]] [-p port] [
    -F alternative ssh_config file] [-t target_path] [[-o <ssh -o options>] ...] [us
er@]hostname
    -f: force mode -- copy keys without trying to check if they are already
        installed
    -n: dry run    -- no keys are actually copied
    -s: use sftp   -- use sftp instead of executing remote-commands. Can be
        useful if the remote only allows sftp
    -x: debug      -- enables -x in this shell, for debugging
    -h|-?: print this help
cj@Workstation:~$
```

- Issue the command similar to this: *ssh-copy-id -i ~/.ssh/id_rsa user@host*
- Once the public key has been configured on the server, the server will allow any connecting user that has the private key to log in. During the login process, the client proves possession of the private key by digitally signing the key exchange.

```
cj@Workstation:~$ ssh-copy-id -i ~/.ssh/id_rsa cj@Workstation
/usr/bin/ssh-copy-id: INFO: Source of key(s) to be installed: "/home/cj/.ss
rsa.pub"
/usr/bin/ssh-copy-id: INFO: attempting to log in with the new key(s), to fi
out any that are already installed
/usr/bin/ssh-copy-id: INFO: 1 key(s) remain to be installed -- if you are p
ed now it is to install the new keys
cj@workstation's password:

Number of key(s) added: 1

Now try logging into the machine, with:  "ssh 'cj@Workstation'"
and check to make sure that only the key(s) you wanted were added.

cj@Workstation:~$
```

- On the local machine, verify that you can SSH with Server 1 and Server 2. What did you notice? Did the connection ask for a password? If not, why?

```
cj@Workstation:~$ ssh cj@Server1
cj@server1's password:
Welcome to Ubuntu 24.04.3 LTS (GNU/Linux 6.14.0-27-generic x86_64)

 * Documentation:  https://help.ubuntu.com
 * Management:     https://landscape.canonical.com
 * Support:        https://ubuntu.com/pro

Expanded Security Maintenance for Applications is not enabled.

Enable ESM Apps to receive additional future security updates.
See https://ubuntu.com/esm or run: sudo pro status

Last login: Fri Aug  8 10:29:43 2025 from 192.168.56.108
cj@Server1:~$
```

Reflections:

Answer the following:

1. How will you describe the ssh-program? What does it do?
 - It gives a secure remote login.
2. How do you know that you already installed the public key to the remote servers?
 - attempting to SSH into the server without being prompted for a password

Part 2: Discussion

Provide screenshots for each task.

It is assumed that you are done with the last activity (**Activity 2: SSH Key-Based Authentication**).

Set up Git

At the heart of GitHub is an open-source version control system (VCS) called Git. Git is responsible for everything GitHub-related that happens locally on your computer. To use Git on the command line, you'll need to download, install, and configure Git on your computer. You can also install GitHub CLI to use GitHub from the command line. If you don't need to work with files locally, GitHub lets you complete many Git-related actions directly in the browser, including:

- Creating a repository
- Forking a repository

- Managing files
- Being social

Task 3: Set up the Git Repository

1. On the local machine, verify the version of your git using the command ***which git***. If a directory of git is displayed, then you don't need to install git. Otherwise, to install git, use the following command: ***sudo apt install git***

```
cj@Workstation:~$ sudo apt install git
[sudo] password for cj:
Reading package lists... Done
Building dependency tree... Done
Reading state information... Done
The following packages were automatically installed and are no longer required
  libgl1-amber-dri libglapi-mesa
Use 'sudo apt autoremove' to remove them.
The following additional packages will be installed:
  git-man liberror-perl
Suggested packages:
  git-daemon-run | git-daemon-sysvinit git-doc git-email git-gui gitk gitweb
  git-cvs git-mediawiki git-svn
The following NEW packages will be installed:
  git git-man liberror-perl
0 upgraded, 3 newly installed, 0 to remove and 1 not upgraded.
Need to get 4,806 kB of archives.
After this operation, 24.5 MB of additional disk space will be used.
Do you want to continue? [Y/n] Y
```

2. After the installation, issue the command ***which git*** again. The directory of git is usually installed in this location: ***user/bin/git***.

```
cj@Workstation:~$ which git
/usr/bin/git
cj@Workstation:~$
```

3. The version of git installed in your device is the latest. Try issuing the command ***git --version*** to know the version installed.

```
cj@Workstation:~$ git --version
git version 2.43.0
cj@Workstation:~$
```

4. Using the browser in the local machine, go to www.github.com.
5. Sign up in case you don't have an account yet. Otherwise, login to your GitHub account.
 - a. Create a new repository and name it as CPE232_yourname. Check Add a README file and click Create repository.

CPE232_Carag Public

main 1 Branch 0 Tags Go to file t +

b. Create a new SSH key on GitHub. Go your profile's setting and click SSH and GPG keys. If there is an existing key, make sure to delete it. To create a new SSH keys, click New SSH Key. Write CPE232 key as the title of the key.

c. On the local machine's terminal, issue the command cat .ssh/id_rsa.pub and copy the public key. Paste it on the GitHub key and press Add SSH key.

```
cj@Workstation:~$ cat .ssh/id_rsa.pub
ssh-rsa AAAAB3NzaC1yc2EAAAQABAAQCTrvibMmMrl+D/Wzh7/umvVnIf7blctpiSutX0P1Gzm

niE2EjpU7P2arwsPJwss4HsgBj10uCndLEQFZBQiqhqJgQMcYNRxE7ZJ1VWhzp8XiIO96lfFzTK/o5n
/w== cj@Workstation
```

d. Clone the repository that you created. In doing this, you need to get the link from GitHub. Browse to your repository as shown below. Click on the Code drop down menu. Select SSH and copy the link.

The screenshot shows the GitHub repository settings page for 'CPE232_Carag'. The 'SSH keys' section is visible, containing a single key entry:

- CPE232**
- SHA256:1A60TGb1T02q5DNbx5MDbFXnRwgE10F/2mr5tzcQlbE
- Added on Aug 15, 2025
- Last used within the last week — Read/write

Below the keys section, a note reads: "Check out our guide to [connecting to GitHub using SSH keys](#) or troubleshoot [common SSH problems](#)".

remote: Counting objects: 100% (3/3), done.
remote: Total 3 (delta 0), reused 0 (delta 0), pack-reused 0 (from 0)
Receiving objects: 100% (3/3), done.
cj@Workstation:~$
```

- f. To verify that you have cloned the GitHub repository, issue the command `ls`. Observe that you have the CPE232_yourname in the list of your directories. Use CD command to go to that directory and LS command to see the file README.md.

```
cj@Workstation:~$ ls
CPE232_Carag  Documents  Music      Public    Templates
Desktop       Downloads   Pictures   snap      Videos
cj@Workstation:~$
```

- g. Use the following commands to personalize your git.
- `git config --global user.name "Your Name"`
 - `git config --global user.email yourname@email.com`
 - Verify that you have personalized the config file using the command `cat ~/.gitconfig`

```
cj@Workstation:~/CPE232_Carag$ cat ~/.gitconfig
[user]
  name = Carag
  email = qcjbcarag@tip.edu.ph
cj@Workstation:~/CPE232_Carag$
```

- h. Edit the README.md file using nano command. Provide any information on the markdown file pertaining to the repository you created. Make sure to write out or save the file and exit.

```
GNU nano 7.2                                         README.md *
# CPE232_Carag
My Favorite color is blue.
```

- i. Use the *git status* command to display the state of the working directory and the staging area. This command shows which changes have been staged, which haven't, and which files aren't being tracked by Git. Status output does not show any information regarding the committed project history. What is the result of issuing this command?

- It displays the state of the working directory and the staging area, it shows the changes that have been staged, not staged and the files that are not being tracked by git.

```
cj@Workstation:~/CPE232_Carag$ git status
On branch main
Your branch is up to date with 'origin/main'.

Changes not staged for commit:
  (use "git add <file>..." to update what will be committed)
    (use "git restore <file>..." to discard changes in working directory)
      modified:   README.md

no changes added to commit (use "git add" and/or "git commit -a")
```

- j. Use the command *git add README.md* to add the file into the staging area.

```
no changes added to commit (use "git add" and/or "git
cj@Workstation:~/CPE232_Carag$ git add README.md
```

- k. Use the *git commit -m "your message"* to create a snapshot of the staged changes along the timeline of the Git projects history. The use of this command is required to select the changes that will be staged for the next commit.

```
cj@Workstation:~/CPE232_Carag$ git add README.md
cj@Workstation:~/CPE232_Carag$ git commit -m "Carl Carag is go
[main 6351742] Carl Carag is good
  1 file changed, 2 insertions(+), 1 deletion(-)
cj@Workstation:~/CPE232_Carag$
```

- I. Use the command `git push <remote><branch>` to upload the local repository content to GitHub repository. Pushing means to transfer commits from the local repository to the remote repository. As an example, you may issue `git push origin main`.

The terminal window shows the command `git push origin main` being run, with the output indicating successful enumeration, counting, writing of objects, and a total of 3 delta objects being packed and reused. The GitHub repository page for "CPE232_Carag" shows a single commit made by "CarlCarag" titled "Carl Carag is good". The README.md file contains the text "Carl Carag is good". The README file contains the text "My Favorite color is blue."

- m. On the GitHub repository, verify that the changes have been made to README.md by refreshing the page. Describe the README.md file. You can notice the how long was the last commit. It should be some minutes ago and the message you typed on the git commit command should be there. Also, the README.md file should have been edited according to the text you wrote.

Reflections:

Answer the following:

3. What sort of things have we done so far to the remote servers using ansible commands?

- I have edited the [README.md](#) in the local machine, and have generated an ssh key pair for authentication. The edited [README.md](#) file from the local machine was then uploaded to the GitHub repository and the commits that are done in the local repository are saved in my Github repository.
4. How important is the inventory file?
- It is important because you can see the changes you commit from the local machine that was being verified in the inventory when you needed to check it there.

Conclusions/Learnings:

I have learned that we may use the ssh keygen pairs to link the repositories from GitHub to the local machine which is a new learning that I have adapted. We may also create in our git a [README.md](#) on the local machine and edit it using the command ***git commit -m "my message"*** to allow the editing in our [README.md](#)
